ABSTRACT

Backgrounds and Purposes: Primary central nervous system lymphoma (PCNSL) is a rare subtype of non-Hodgkin’s lymphoma. The prognosis of PCNSL is poor and heterogeneous. MicroRNA is associated with prognosis of various cancers. Our study is the first time to compare circulating microRNAs of PCNSL patients with different prognosis using miRNA microarray scanning and find novel microRNAs associated with prognosis of PCNSL by further large-scale validation.

Materials and Methods: From a retrospective cohort, we collected the clinical data of patients who were diagnosed as PCNSL in Huashan Hospital between January 2007 and June 2016. We collected clinical data and blood samples from residual blood routine test of PCNSLs. First, we compared circulating microRNAs between patients with different overall survival (OS) using miRNA microarray scanning. Second, PCR assay was used for miRNAs quantification in blood sample from 6 patients that had long overall survival and other 6 patients that had short overall survival. Further miRNA validation was made by PCR assay in blood sample from 94 patients to validate prognostic value of miRNAs in PCNSLs. The Kruskal-Wallis and Mann-Whitney U tests were used for quantitative parameters and the χ2 square test was used for non-quantitative parameters. Univariate analysis was performed using log-rank test, and survival distributions were analyzed by the Kaplan-Meier curve and log-rank test. Multivariate analysis was done by Cox regression model.

Results: A total of 90 differentially expressed miRNAs were identified, including 24 up-regulated miRNAs and 66 down-regulated miRNAs using miRNA microarray scanning. Then PCR assay was used for 10 differentially expressed miRNAs quantification in blood sample from 6 patients that had long overall survival and 6 patients that had short overall survival. Mir-21, mir-129-5p, mir-144-5, mir-363-5p, mir-409-3p, mir-1246, mir-1299 and mir-1825 showed no differences between 2 groups, while the expression of mir-455-3P and mir-940 between 2 groups are significantly different (P<0.05). Further validation in 94 patients showed median OS in miR-940 overexpression group was 91 months and in miR-940 low-expression group was 28 months (P=0.0005), while median PFS in miR-940 overexpression group was 25 months and in miR-940 low-expression group was 16 months (P=0.0292). Multivariate analysis of COX model showed miR-940 was independent factors for OS and PFS.

Conclusion: Circulating mir-940 had prognostic value in PCNSL and was an independent prognostic factor for PCNSL.

Introduction

Primary central nervous system lymphoma (PCNSL) is a rare extranodal form of non-Hodgkin lymphoma (NHL), which occurs intracerebrally or intraocularly, with poor long-term survival. These lymphomas exclusively arise in the central nervous system (CNS) such as the brain parenchyma [1], spinal cord, eyes and/or cranial nerves. Historically, approximately 90% of PCNSL are diffuse large B cell lymphoma (DLBCL). The prognosis of PCNSL is poor and heterogeneous and PCNSL patients are often lack of specific, sensitive, noninvasive manifestations to diagnosis and prognosis. MiRNAs are small regulatory, noncoding RNAs. It is believed that miRNAs primarily affect the stability of mRNA and/or the initiation and progression of protein translation [2-6]. Even though the biological function of miRNA is yet to be fully understood, it has been shown that miRNAs play multiple roles in cancer genesis, development, invasion and metastasis [7-9]. However, there are few studies on miRNAs involved in prognosis of PCNSL.

In the current study, we established retrospective cohort of PCNSL patients. Patients with poor overall survival (OS) were classified as the case group, whereas patients with good OS were classified as the control group. We studied the different microRNA gene expression of patients in the case and control groups to gain insight into the specific miRNA associated with PCNSL prognosis.

Materials and Methods

■ Patients and ethics statement

A total of 151 patients newly diagnosed with PCNSL between July 2007 and June 2016 in Huashan Hospital were retrospectively enrolled in this study, with the enrollment criteria of HIV-negative and non-immunosuppression-related PCNSL. These patients were pathologically reconfirmed according to the 2008 WHO classification of lymphomas. Clinicopathological data were collected, including clinical presentations, diagnoses, regimens, therapeutic outcomes, second-line treatments, toxicity reactions, and survival durations. Signed informed consent was obtained from all patients or guardians. All patients underwent gadolinium-enhanced cranial magnetic resonance imaging (MRI) scan and/or positron emission tomography/computed tomography (PET/CT) before and after chemotherapy to evaluate the response to treatment. Serum lactate dehydrogenase (LDH), total creatinine clearance (CCr), B ultrasound of lymph nodes and abdomen, slit-lamp examination, as well as bone marrow biopsy and aspiration were also conducted in all patients.

■ RNA extraction

The total RNA from peripheral blood mononuclear cells was extracted using TRizol (Invitrogen, Paisley, U.K.) according to the manufacturer’s protocol. Aliquots of the RNA samples were conserved for quality evaluation using Agilent 2100 Bioanalyzer (Agilent Technologies, Palo Alto, CA).

■ Array hybridization, data analyses and target prediction of miRNAs

To assess the level and composition of miRNA, miRNA arrays from Agilent Technologies were used. The RNA samples were labeled and processed according to manufacturer’s recommended protocols. In brief, ≈100 ng of total RNA was dephosphorylated with calf intestinal alkaline phosphatase, followed by denaturing with heat in the presence of dimethyl sulfoxide (DMSO). A cyanine dye, cyanine3-cytidine bisphosphate (pCp), was then joined to the dephosphorylated single-stranded RNA (including miRNA) by T4RNA ligase. Micro BioSpin 6 columns (Bio-Rad) were used to remove any unincorporated cyanine dye from the samples. The purified labeled miRNA probes were hybridized to 8 × 15 K human miRNA microarrays in a rotating hybridization oven at 20 rpm for 20 h at 55°C. After hybridization, the arrays were washed in Agilent gene expression (GE) Wash Buffer 1 with TritonX-102, followed by Agilent GE Wash Buffer 2 with Triton X-102. After washing, all slides were immediately scanned at 5 μm resolution by using a PerkinElmer ScanArray Express array scanner. The resulting images were quantified by using Agilent’s Feature Extraction software. The differentially expressed miRNAs were identified using Agilent miRNA gene arrays protocol. To increase the reliability of the data, miRNA species with hybridization intensities<1.5 times the average hybridization intensity (mean) were excluded from analysis. The miRNA clustering analysis was performed with the Hierarchical clustering algorithm provided in Multi Experiment Viewer, MeV4.0 software package (www.tm4.org/mev.html). After screening the differentiated miRNA, we predicted the
targeting genes using targets can software. Sites with $P_{\text{adj}}>0.75$ are with higher probability of preferential conservation.

**Statistical analysis**

Descriptive and explorative data analyses of all parameters were done. Quantitative parameters were tested for normal distribution. The Kruskal-Wallis and Mann-Whitney U tests were used for quantitative parameters; the $\chi^2$ square test and the Fisher’s test for non-quantitative parameters. Survival and follow-up were calculated from the date of PCNSL diagnosis to the time of death, recurrence, progression, or last follow-up. Univariate analysis was performed using log-rank test, and survival distributions were analyzed by the Kaplan-Meier curve and log-rank test. Multivariate analysis was done by Cox regression model. All tests were two-sided and $P<0.05$ was considered to be statistically significant. All statistical analyses were performed with Stata (Version 12.0) and Graph Pad Prism (Version 6.0).

**Results**

From the above retrospective cohort of PCNSL patients, paired patients were chosen for miRNA microarray screening according to age, gender, ECOG, Pathology, LDH level, CSF protein level, and Involvement of deep structures (Table 1). Long OS included patients with more than 3 years OS, while short OS included patients with less than 1 years OS. We adapted a microarray platform from Agilent to profile the miRNA spectra. Excluding any miRNA with hybridization intensity <1.5 times the global mean intensity, there were 90 miRNAs to be significantly differentially expressed between two group, including 66 down-regulated miRNA and 24 upregulated miRNA (Figure 1). The main characteristics of paired patients for miRNA microarray assay are listed in Table 1. The identities of miRNAs are listed on the right, whereas the sample names are on the bottom.

Cluster analysis of above 90 miRNAs resulted in a subset of 10 differentially expressed miRNAs, including mir-21, mir-129-5p, mir-144-5, mir-363-5p, mir-409-3p, mir-455-3p, mir-940, mir-1246, mir-1299 and mir-1825. Then validation of these 10 differentially expressed miRNAs was made in 6 patients with long OS and 6 patients with short OS using PCR assay. The main characteristics of paired patients for miRNA microarray assay are listed in Table 2. Mir-21, mir-129-5p, mir-144-5, mir-363-5p, mir-409-3p, mir-1246, mir-1299 and mir-1825 showed no differences between 2 groups, while the expression of mir-455-3p and mir-940 between 2 groups are significantly different ($P<0.05$) (Table 3).

Kaplan-Meier curves of 12 patients showed median OS in miR-455-3p overexpression group and low-expression group was 10 months and 91 months, respectively. Median OS in miR-940 overexpression and low-expression group was 91 months and 10 months, respectively ($P \geq 0.05$) (Figure 2).

Further validation of mir-455-3p and mir-940 was made by Kaplan-Meier in 94 patients. Median OS in miR-455-3p overexpression group was 28 months and in miR-940 low-expression group was 56 months ($P=0.12$). And median PFS in miR-455-3p overexpression group was 23 months and in miR-940 low-expression group was 16 months ($P=0.16$) (Table 4).

Median OS in miR-940 overexpression group was 91 months and in miR-940 low-expression group was 28 months ($P=0.0003$). And median PFS in miR-940 overexpression group was 25 months and in miR-940 low-expression group was 16 months ($P=0.0292$) (Figure 3).

Discussion

The prognosis of PCNSL is poor and heterogeneous. PCNSL patients are often lack of specific, sensitive, noninvasive manifestations to diagnosis and prognosis. Recently, research studied the prognosis value of clinical, biochemical and immune examination and found that some factors are involved, including the patient’s age, performance status (PS), serum LDH levels, cerebrospinal fluid protein concentration, deep brain and etc. MiRNAs are small regulatory, noncoding RNAs and play multiple roles in cancer genesis, development, invasion and metastasis. Compared with mRNA, miRNAs are more stable and specific so as to be an ideal tumor marker. However, there are few studies on miRNAs involved in prognosis of PCNSL.
In the current study, it is the first time to comparing circulating microRNAs of PCNSLs that had different prognosis using miRNA microarray scanning and finding novel microRNAs associated with prognosis of PCNSL by further large-scale validation. We identified 90 miRNAs to be significantly differentially expressed between two groups with long and short OS. We finally screened a subset of 10 miRNAs for further validation in 6 patients with long OS and 6 patients with short OS, showing the expression of mir-455-3P and mir-940 between 2 groups are significantly different (P<0.05) (Table 3).

Recently study showed mir-455-3p can promote prostate cancer cell invasion and metastasis by targeting the tumor suppressor gene EL24, and high expression of mir-455-3p is associated with poor prognosis [10]. In colon cancer cell lines, mir-455-3p induces apoptosis and inhibits cell proliferation by targeting the tumor suppressor gene HCT116 [11]. In glioblastoma cells resistant to temozolomide, mir-455-3p was significantly higher and overexpression of mir-455-3p showed a cytotoxic effect when temozolomide was used [12]. High expression of mir-455-3p is also observed in basal cell carcinoma of the skin [13]. In particular, in DLBCL patients with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone) treatment, high expression of blood

In the current study, it is the first time to comparing circulating microRNAs of PCNSLs that had different prognosis using miRNA microarray scanning and finding novel microRNAs associated with prognosis of PCNSL by further large-scale validation. We identified 90 miRNAs to be significantly differentially expressed between two groups with long and short OS. We finally screened a subset of 10 miRNAs for further validation in 6 patients with long OS and 6 patients with short OS, showing the expression of mir-455-3P and mir-940 between 2 groups are significantly different (P<0.05) (Table 3).
circulating mir-455-3p is associated with high relapse [14]. Our study showed patients with high mir-455-3p expression had short OS and long PFS although there is no statistic significance.

Expression of mir-940 was found lower in prostate cancer tissues than normal tissues, and the mechanism may be that mir-940 can inhibit cancer cell migration and invasion by regulating the migration and invasion of enhanced gene 1 (Migration and invasion enhancer 1, MIEN1) [15]. In pancreatic ductal adenocarcinoma, high expression of mir-940 also inhibited pancreatic ductal adenocarcinoma cell growth, whereas low mir-940 expression was associated with a low survival rate [16]. However, the results of other study in gastric cancer are different from those of prostate cancer and pancreatic ductal adenocarcinoma, that high expression of mir-940 is associated with poor prognosis. The authors suggest that mir-940 can enhance the ability of invasion and metastasis of gastric cancer by down-regulating the expression of zinc finger transcription factor 24 (Zinc, Finger, Transcription, Factor, 24, ZNF24) [17]. A study by Xie et al. shows that mir-940 expression is up regulated in saliva of patients with pancreatic cancer and can be used in the diagnosis of early pancreatic cancer [19]. Our study showed patients with low mir-940 expression had long OS although there is no statistical significance (P=0.16).

In all, our study showed circulating mir-940 is a potential prognostic biomarker for PCNSL; nevertheless, our research has intrinsic limitations in consideration that it is a retrospective, single-institution analysis. The matching of the two patient cohorts are suboptimal by reason that patients were not prospectively assigned to the different treatment groups using prognostic factors for randomization. Thus, future well-controlled prospective studies are required to confirm the current data.

**Authorship**

Yan MA and Dina Suolitiken analyzed patients’ data and wrote the manuscript. Xiaoping Xu and Bobin Chen reviewed and supervised research and approved the manuscript. Lu Zhang, Hui Kang, Zhiguang Lin and Qian Wang participated in the implementation of the treatment.

**Conflict of Interest**

The authors declare that they have no conflict of interest.
